

Cristina Nita-Rotaru

CS526: Information security

Anonymity systems.

Based on slides by Chi Bun Chan

1: Terminology.

Anonymity

Anonymity (“without name”) means that a person is not identifiable within a set of subjects

- ▶ **Unlinkability of action and identity**
 - ▶ For example, sender and his email are no more related after adversary's observations than they were before
 - ▶ Who talks to whom
- ▶ **Unobservability**
 - ▶ Adversary cannot tell whether someone is using a particular system and/or protocol

Needs for anonymity

- ▶ Hiding identity
- ▶ Privacy
- ▶ Security
- ▶ Degree of innocence or deniability

Relevant applications

- ▶ Anonymizing bulletin board and email
- ▶ Electronic voting
- ▶ Incident reporting
- ▶ Anonymous e-commerce
- ▶ Private information retrieval
- ▶ Anonymous communication

Privacy on public networks

- ▶ Internet is designed as a public network
 - ▶ Wi-Fi access points, network routers see all traffic that passes through them
- ▶ Routing information is public
 - ▶ IP packet headers identify source and destination
 - ▶ Even a passive observer can easily figure out who is talking to whom
- ▶ Encryption does not hide identities
 - ▶ Encryption hides payload, but not routing information
 - ▶ Even IP-level encryption (tunnel-mode IPsec/ESP) reveals IP addresses of IPsec gateways

Anonymity metrics in communication

- ▶ **Basic metrics:**

- ▶ Sender anonymity - who sends what
- ▶ Receiver anonymity - who receives what
- ▶ Unlinkability (relationship anonymity) - who talks to whom

- ▶ **Providing sender anonymity and unlinkability are desirable enough for common Internet activities**

- ▶ **Goals:**

- ▶ The identities of the communicating parties should stay anonymous to the outside community
- ▶ Even the parties in communication may not know each other's real identity

Types of adversary

▶ **Passive/Active**

- ▶ **Passive:** eavesdrop traffic
- ▶ **Active:** able to observe, delay, alter and drop messages in the system

▶ **Local/Global**

- ▶ **Local:** able to observe traffic to/from user's network link, within LAN
- ▶ **Global:** able to observe effectively large amount or all network links, across LAN boundaries

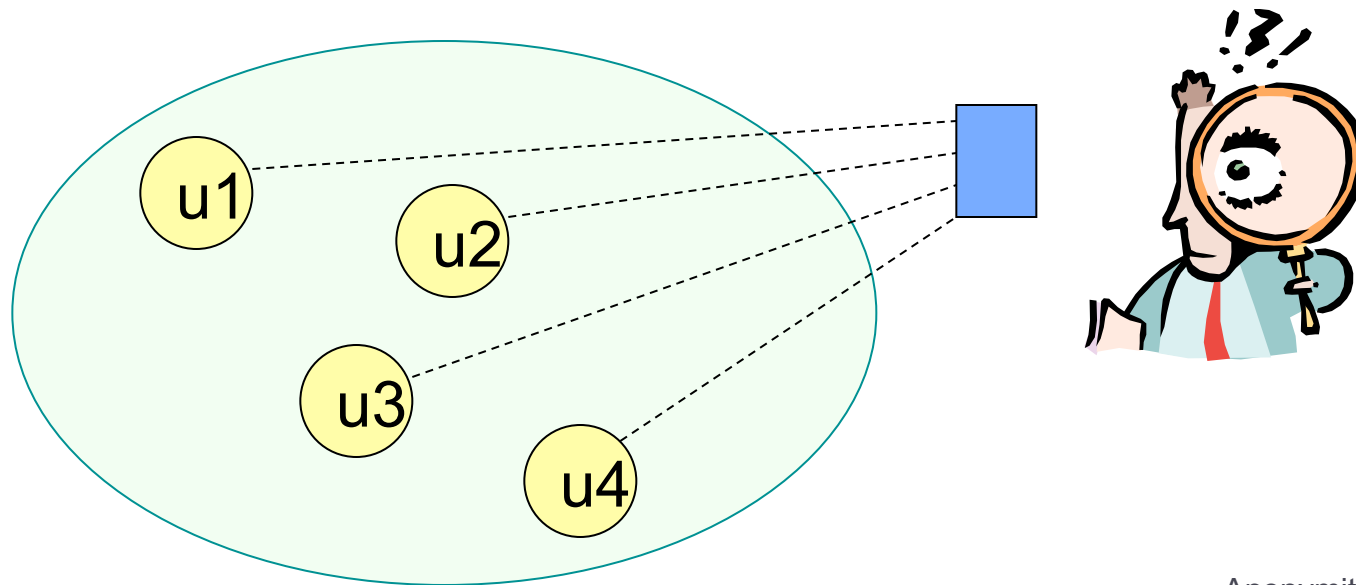

▶ **Internal/External**

- ▶ **Internal:** participants in the anonymity system, adversary-operated nodes
- ▶ **External:** not participate in the protocol but may be able to observe, inject or modify traffic in the system

2: Anonymity systems.

Anonymity set

- ▶ Hiding ones action in many others' actions
- ▶ Anonymity set: a group of users in which every one is equally-probable to be associated with a given action
⇒ every one has certain degree of innocence or deniability to an action

MIX-based systems

- ▶ Concept of using relay servers (MIXes) for anonymous communication
- ▶ Introduced by David Chaum (1981)
- ▶ Goals
 - ▶ Sender anonymity
 - ▶ Unlinkability against global eavesdroppers
- ▶ Idea: Messages from sender “look” (contents, time) differently than messages to recipient

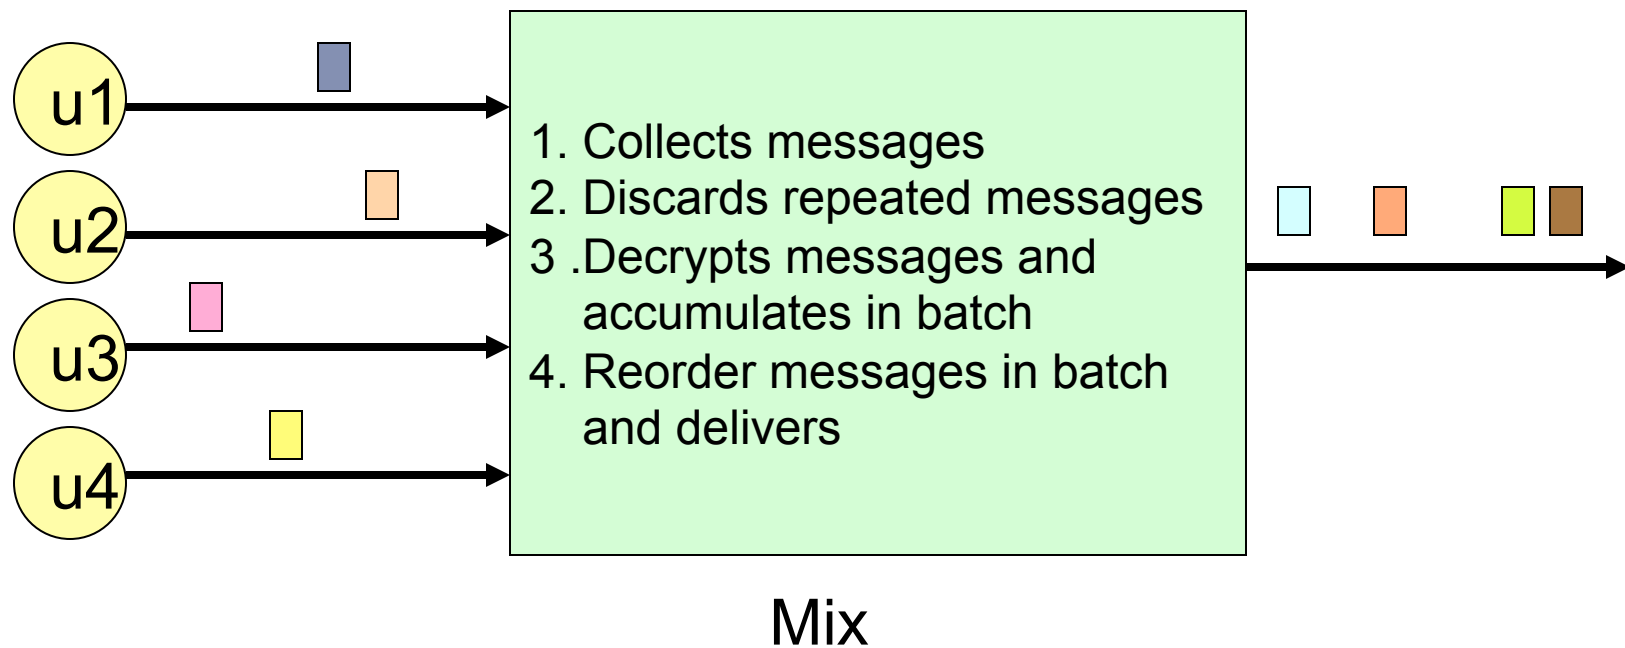

MIX – basic operations

- ▶ A mix is a store-and-forward relay
- ▶ Batching
 - ▶ collect fixed-length messages from different sources
 - ▶ accumulate a batch of n messages
- ▶ Mixing
 - ▶ cryptographically transform collected messages
 - ▶ forwarding messages to their recipients in random order

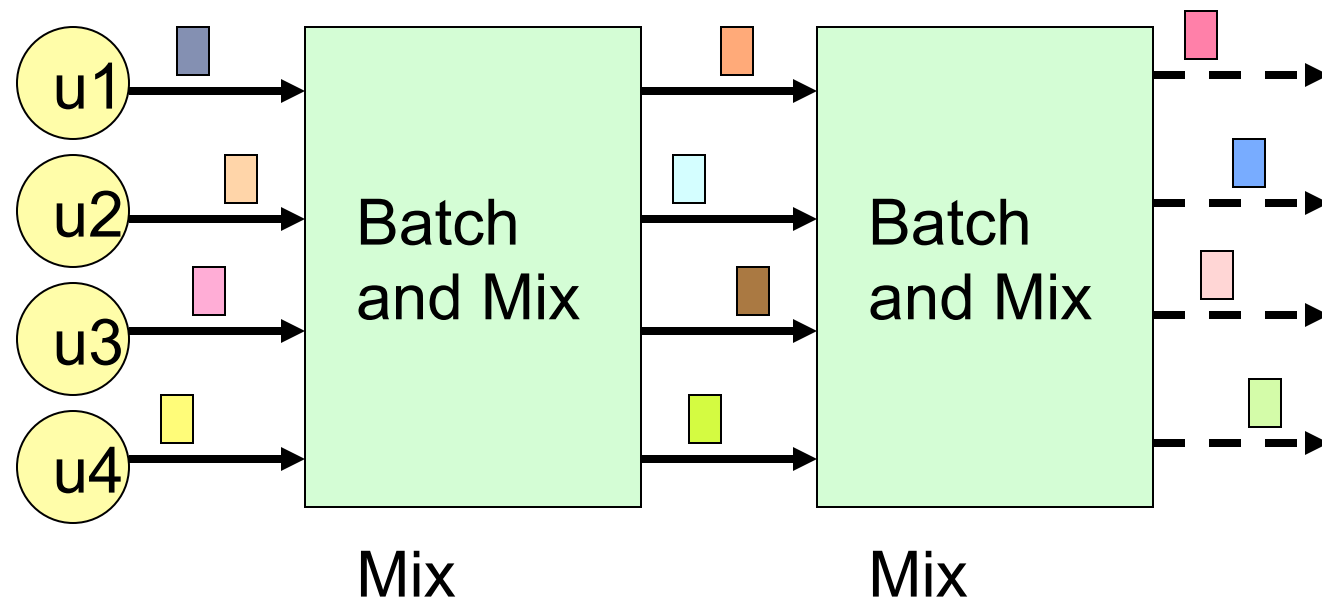

MIX - example

- ▶ Each mix has a public key
- ▶ Each sender encrypts its message (with randomness) using public key of mix

MIX - variants

- ▶ Single mix (also single point of trust, attack and failure)
- ▶ Mix cascade
- ▶ Mix network
- ▶ Different ways of batch and mix operations

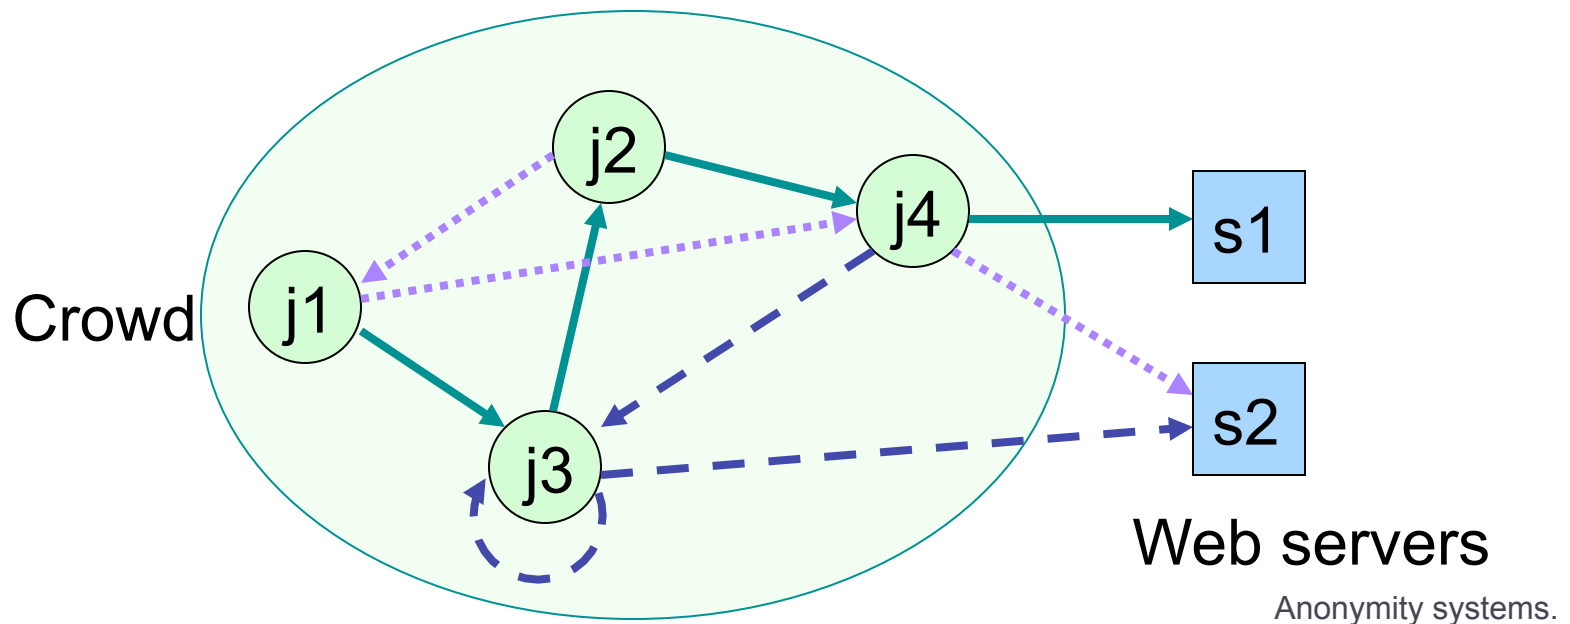

MIX (cont.)

- ▶ Traditional designs are message-based
- ▶ Usually high latency and asynchronous due to batch and mix operations
 - ▶ may be acceptable for applications like email
 - ▶ frustrating user experience in low latency or interactive applications: web browsing, instant messaging, SSH
- ▶ Alternatives: circuit-based designs

Crowds

- ▶ Anonymous web browsing
- ▶ Dynamic collecting users (jondo) in a group (crowd)
- ▶ Member list maintained in a central server (blender)
- ▶ Idea: Who is the initiator?

Crowds (cont.)

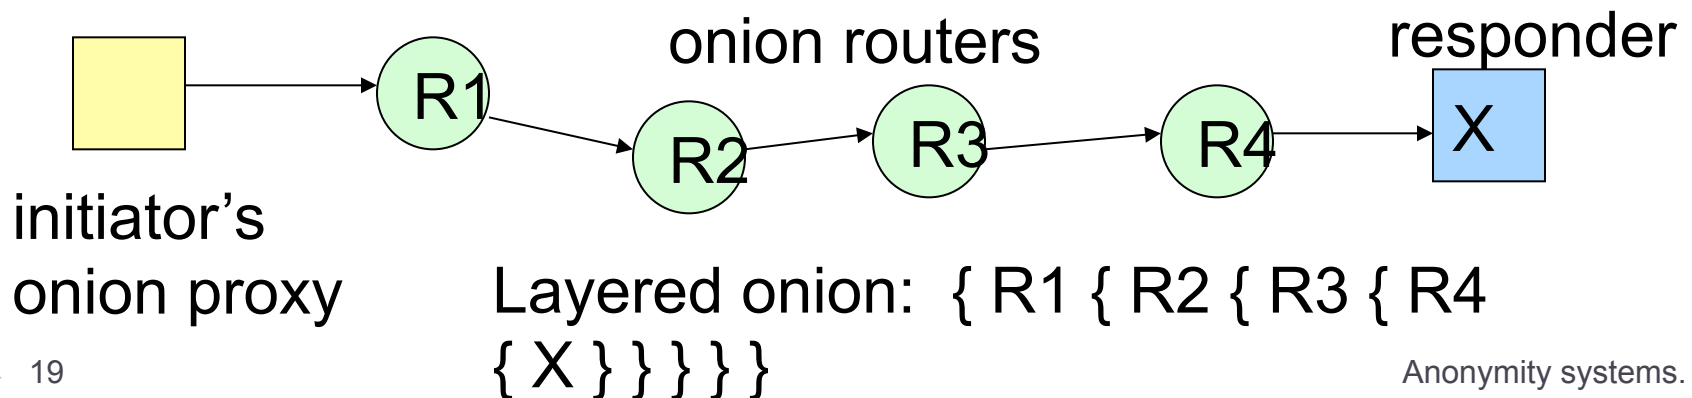

- ▶ Initiator submits request to a random member
- ▶ Upon receiving a request, a member either:
 - ▶ forwards to another random member ($p = pf$)
 - ▶ submits to end server ($p = 1 - pf$)
- ▶ A random path is created during the first request, subsequent requests use the same path; server replies using the same path but in reverse order
- ▶ Link encryption of messages with a shared key known to all members

Onion routing

- ▶ A (small) fixed core set of relays
 - ▶ Core Onion Router (COR)
- ▶ Designed to support low-latency service
- ▶ Initiator defines an anonymous path for a connection through an “onion”
- ▶ An onion is a layered structure (recursively encrypted using public keys of CORs) that defines:
 - ▶ path of a connection through CORs
 - ▶ properties of the connection at each point, e.g. cryptographic algorithms, symmetric keys

Onion routing (cont.)

- ▶ Initiator's onion proxy (OP)
 - ▶ connects to COR
 - ▶ initiates a random circuit using an onion
 - ▶ converts data to fixed size cells
 - ▶ performs layered encryption, one per router
- ▶ Circuit-based multi-hop forward
 - ▶ Each COR decrypts and removes a layer of received cells, then forwards to next COR

Tarzan & MorphMix

- ▶ Similar to Onion routing, Mix-net approach but extended to peer-to-peer environment
 - ▶ Again, layered/nested encryption with multi-hop forwarding
- ▶ All peers are potential message originators and relays
 - ▶ More potential relays than a small fixed core set
 - ▶ More scalable
 - ▶ Hide one's action in a large dynamic set of users
- ▶ Tarzan targets at network layer while MorphMix runs at application layer

Tarzan & MorphMix (cont.)

- ▶ Larger dynamic set of unreliable nodes
- ▶ More efforts to defense against colluding nodes (dishonest or adversary controlled)
 - ▶ Restricted peer-selection in Tarzan
 - ▶ Collusion detection mechanism in MorphMix

3: Traffic analysis.

Attacks on anonymity systems

- ▶ **Degrading the quality of anonymity service**
 - ▶ Break sender/receiver anonymity, unlinkability
 - ▶ Control anonymity to certain level
 - ▶ Traffic analysis, traffic confirmation
- ▶ **Degrading the utilization of anonymity system**
 - ▶ Decrease the performance, reliability and availability of system, so as to drive users not using the service
 - ▶ Denial-of-Service attacks

Traffic analysis

- ▶ If one is interested in breaking the anonymity ...
- ▶ Based on features in communication traffic, one may infer
 - ▶ who's the initiator \Rightarrow NO sender anonymity
 - ▶ who's the responder \Rightarrow NO receiver anonymity
 - ▶ an initiator-responder mapping \Rightarrow NO unlinkability

Common vulnerabilities

- ▶ **Message features**
 - ▶ distinguishable contents, size
- ▶ **Communication patterns**
 - ▶ user online/offline period
 - ▶ send-receive sequence
 - ▶ message frequencies, e.g. burst stream
- ▶ **Properties/constraints in anonymity systems**
 - ▶ low-latency requirement
 - ▶ link capacity and traffic shaping

Attacks on message features

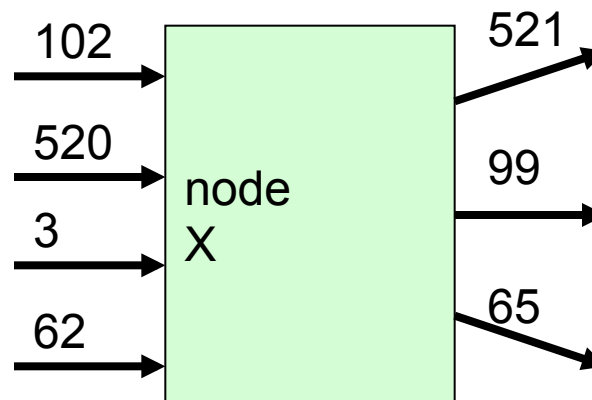

- ▶ If a message itself reveals one's identity or more, anonymity is defeated regardless of the strength of an anonymity system!
- ▶ Message features
 - ▶ size, format, writing style ..., etc
- ▶ Message size
 - ▶ Varieties of message sizes may help linking a message to some application or sender
 - ▶ Fixed by constant-size message padding

Distinguishable message contents

- ▶ **Message contents**
 - ▶ may expose user information or the route of a message
 - ▶ e.g. host information, Referer, User-Agent fields in HTTP header
- ▶ **Active adversary can perform message tagging attack**
 - ▶ Alter bits in message header/payload
 - ▶ Recognize altered messages to exploit the route
- ▶ **Solutions**
 - ▶ Proper message transformation: e.g. encryption
 - ▶ Removal of distinguishable information: e.g. Privoxy (privacy enhancing proxy)

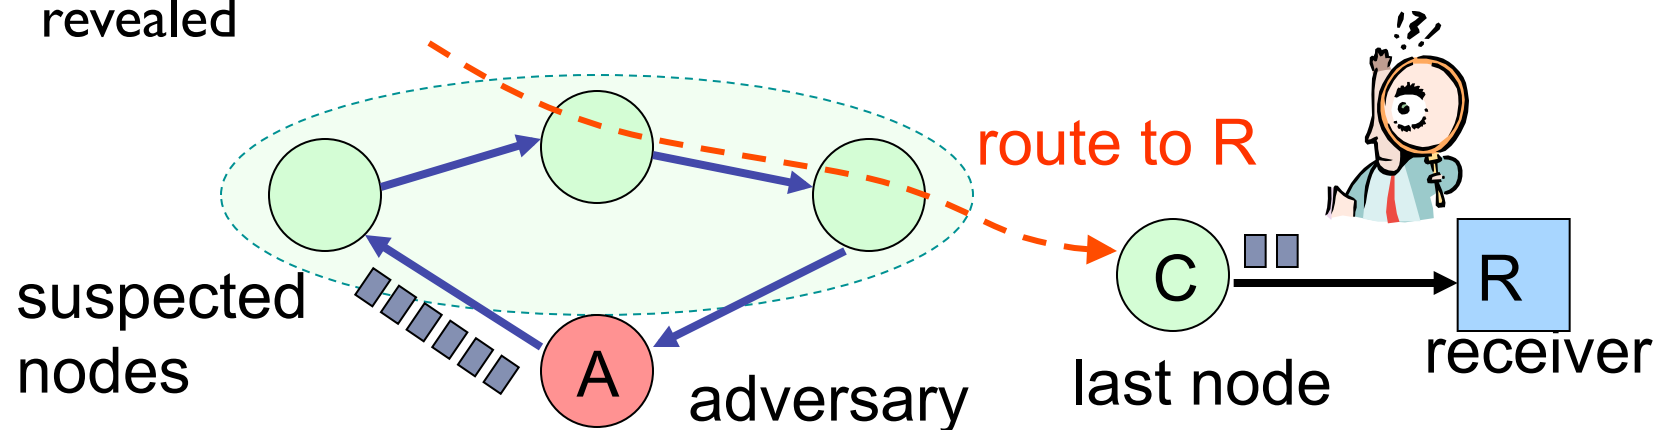

Packet counting attack

- ▶ Count the number of messages entering a node and leaving an anonymous tunnel
- ▶ Constant link padding may help:
 - ▶ Two nodes exchange a constant number of same-sized packets per time unit
 - ▶ Generate dummy traffic on idle or lightly loaded links
 - ▶ Costly
 - ▶ Still vulnerable to other attacks, e.g. latency attacks

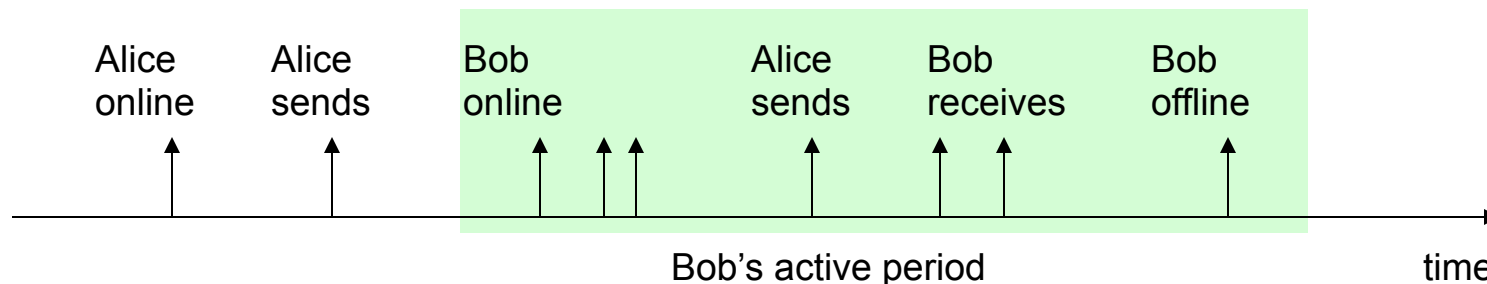

Clogging attack

- ▶ Observe traffic between a certain last node C and end receiver R
- ▶ Create a route through a set of suspected nodes
- ▶ Clog the route with high volume of traffic
- ▶ Decrease in throughput from C to R may indicate at least one node in the suspected route belongs to a route containing C
- ▶ Continue with different sets of nodes until a route to R is revealed

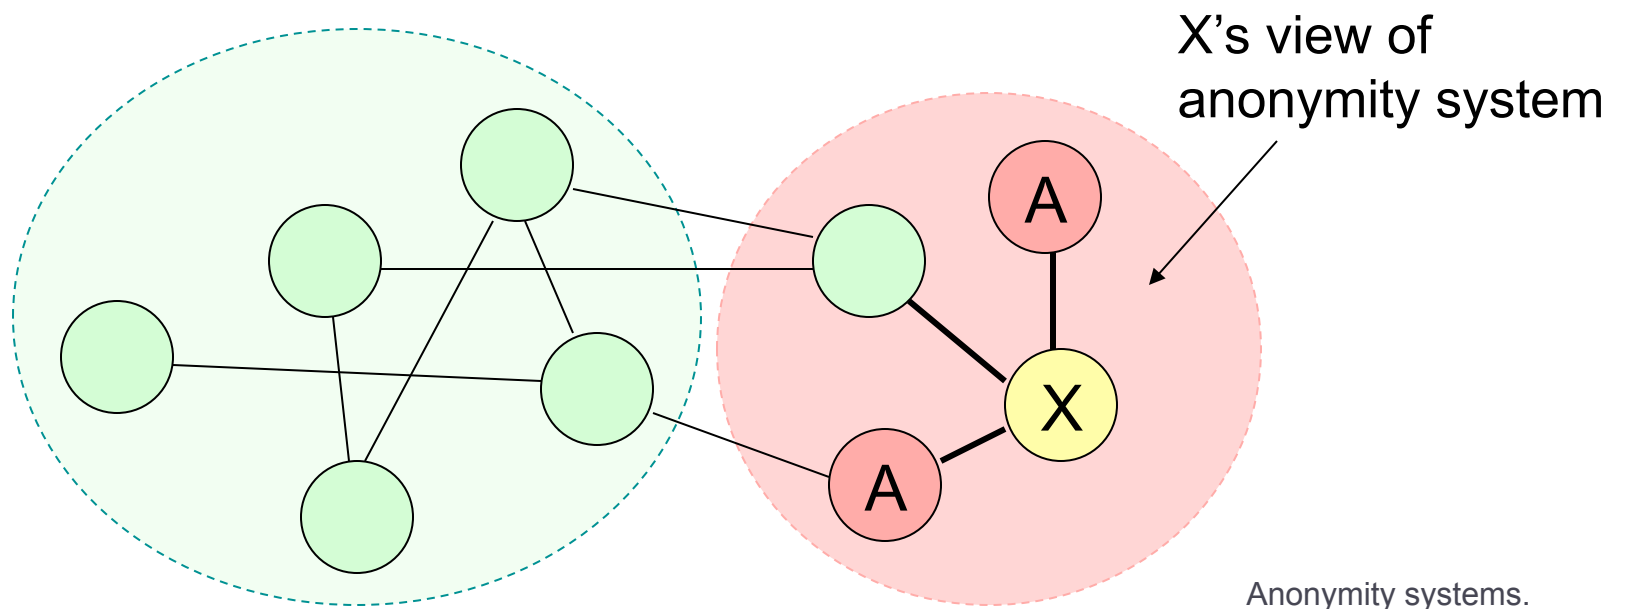

Intersection attacks

- ▶ **Communication pattern**
 - ▶ Users join and leave the system from time to time
 - ▶ Users are not active in communication all the time
 - ▶ Some receivers receive messages after some senders transmit messages
- ▶ **Intersecting sets of possible senders over different time periods → anonymity set shrinks**
- ▶ **Short term vs Long term**

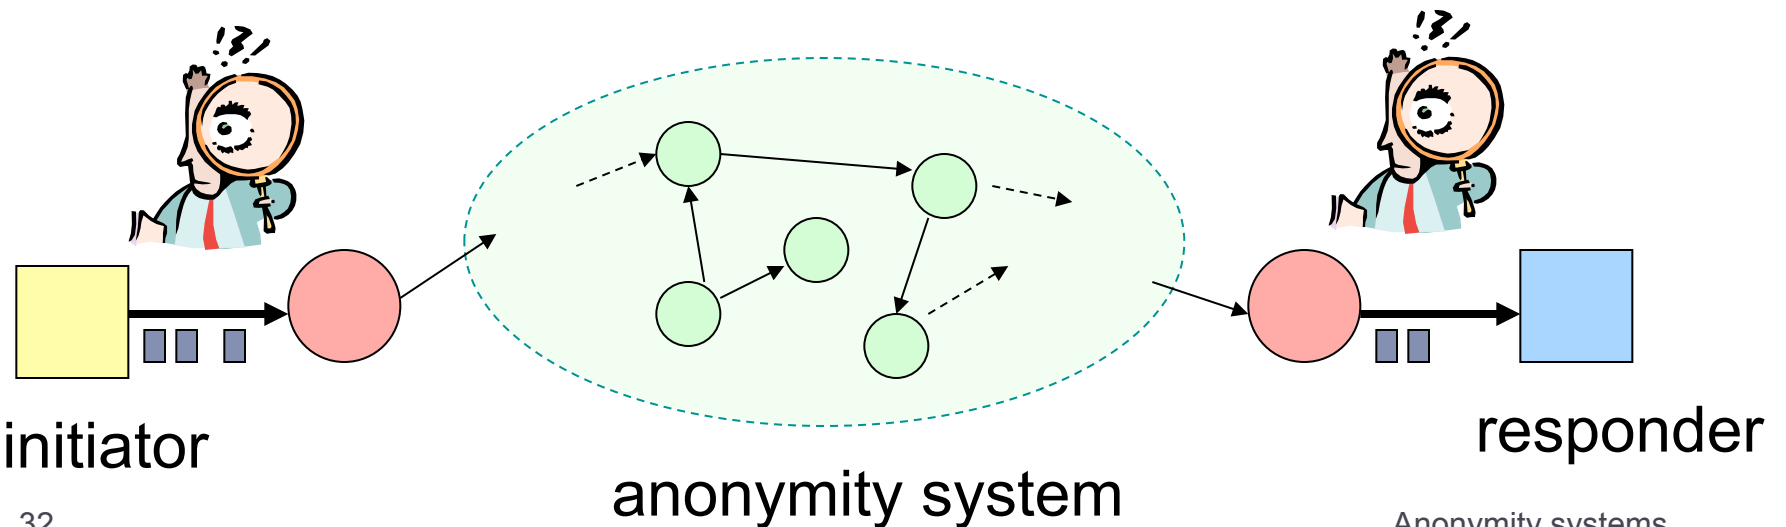

Partition attack on client knowledge

- ▶ Render inconsistent views of anonymity system on clients
 - ▶ e.g. member list on directory server
- ▶ Identify clients who always choose a particular subset of neighbors

Attacks on endpoints

- ▶ Sometimes referred as traffic confirmation rather than traffic analysis
- ▶ Suppose an adversary controls the first and the last node of a route
- ▶ Observe the traffic entering the first node and leaving the last node

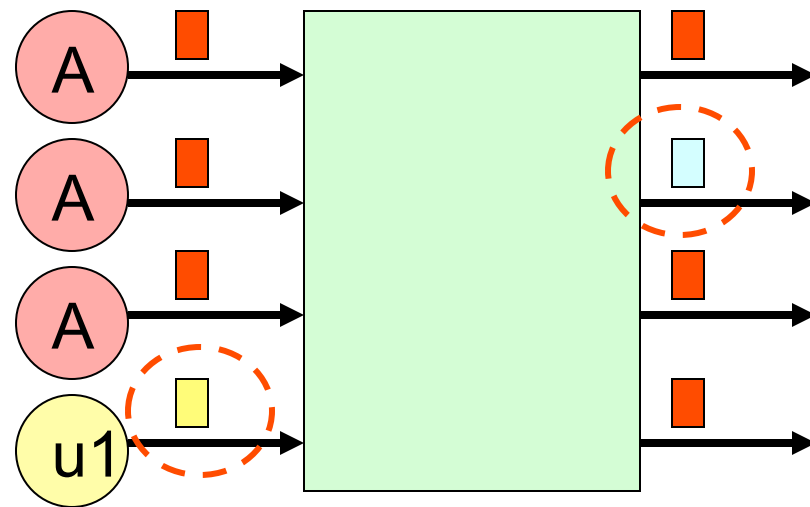

Anonymity systems.

Attacks on endpoints (cont.)

- ▶ Correlate the timings of a message entering the first node with those coming out of the last node
 - ▶ Packet counting attack, Timing attacks, Message frequency attack
- ▶ An adversary may be able to:
 - ▶ figure out some input message to output message mappings
 - ▶ rule out some potential senders or receivers from the anonymity sets
 - ▶ link a particular pair of sender and receiver
- ▶ An active adversary may increase the chance of success and speedup the analysis by delaying and dropping messages, flooding several nodes and links

Node flushing attack

- ▶ Intended to defeat MIX-based systems
- ▶ Flooding attack, $(n-1)$ attack
- ▶ Flood a node with identifiable fake messages but leave a room for a single message to be traced
- ▶ Link user's input message with messages leaving the node

Mix

Anonymity systems.

Trickle attack

- ▶ Trickle, flushing attack - referred as blending attack
- ▶ Suppose a MIX accumulates and emits messages in rounds
- ▶ An active attacker holds a target message until the mix emits a batch of messages
- ▶ He then submits target message to mix while blocking other incoming messages
- ▶ Only the target message is emitted in the next round
- ▶ Requires control over traffic flow - practical to launch?

More attacks ...

- ▶ The “Sting” Attack
- ▶ The “Send n’ Seek” Attack
- ▶ Active Attacks Exploiting User Reactions
- ▶ Denial of Service Attack
- ▶ Social Engineering

- ▶ Alternative attack goal:
 - ▶ Drive users to less secure anonymity systems or not using anonymity service at all

4: Tor: The Second-Generation Onion Router

R. Dingledine, N. Mathewson, P. Syverson

Slides by Vitaly Shmatikov

Disadvantages of Basic Mixnets

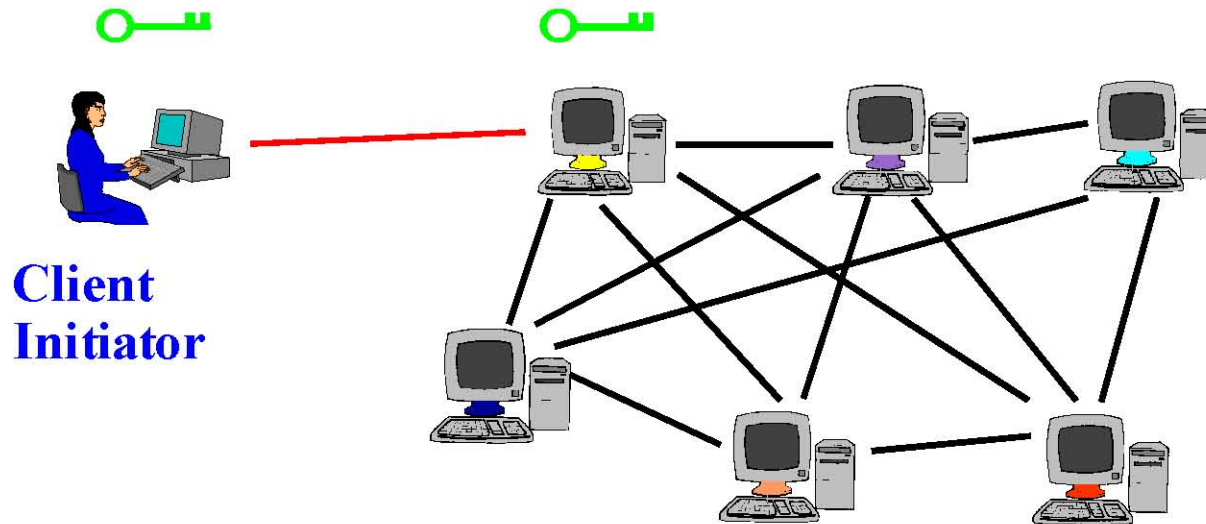

- ▶ Public-key encryption and decryption at each mix are computationally expensive
- ▶ Basic mixnets have high latency
 - ▶ Ok for email, not Ok for anonymous Web browsing
- ▶ Challenge: low-latency anonymity network
 - ▶ Use public-key cryptography to establish a “circuit” with pairwise symmetric keys between hops on the circuit
 - ▶ Then use symmetric decryption and re-encryption to move data messages along the established circuits
 - ▶ Each node behaves like a mix; anonymity is preserved even if some nodes are compromised

Tor

- ▶ Deployed onion routing network
 - ▶ <http://torproject.org>
 - ▶ Specifically designed for low-latency anonymous Internet communications
- ▶ Running since October 2003
 - ▶ Thousands of relay nodes, 100K-500K? of users
- ▶ Easy-to-use client proxy,
- ▶ integrated Web browser

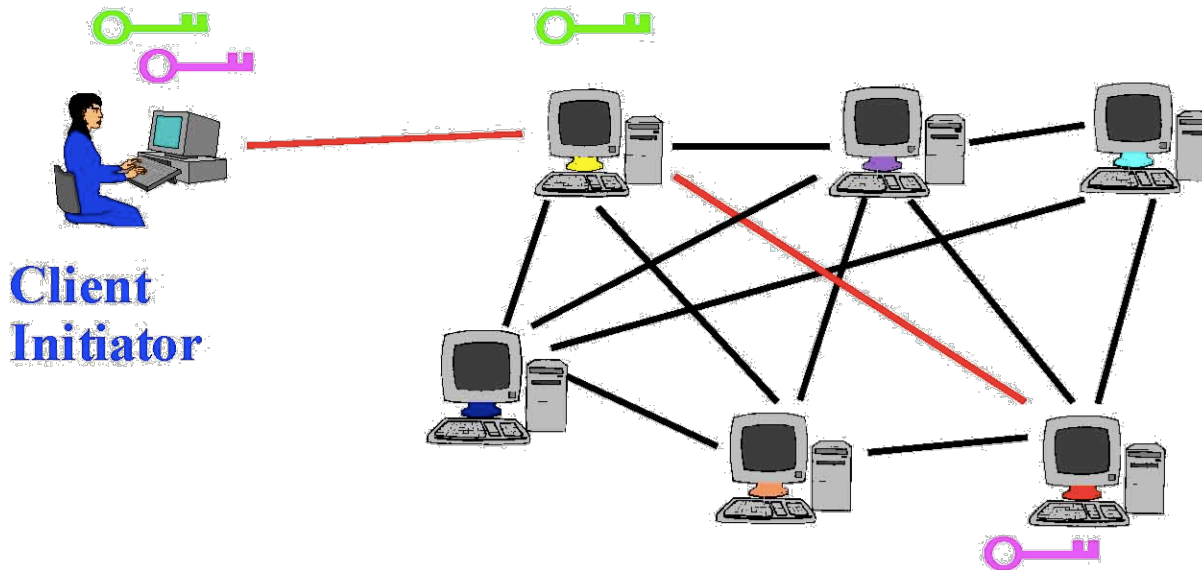

Tor circuit setup (1)

- ▶ Client proxy establish a symmetric session key and circuit with relay node #1

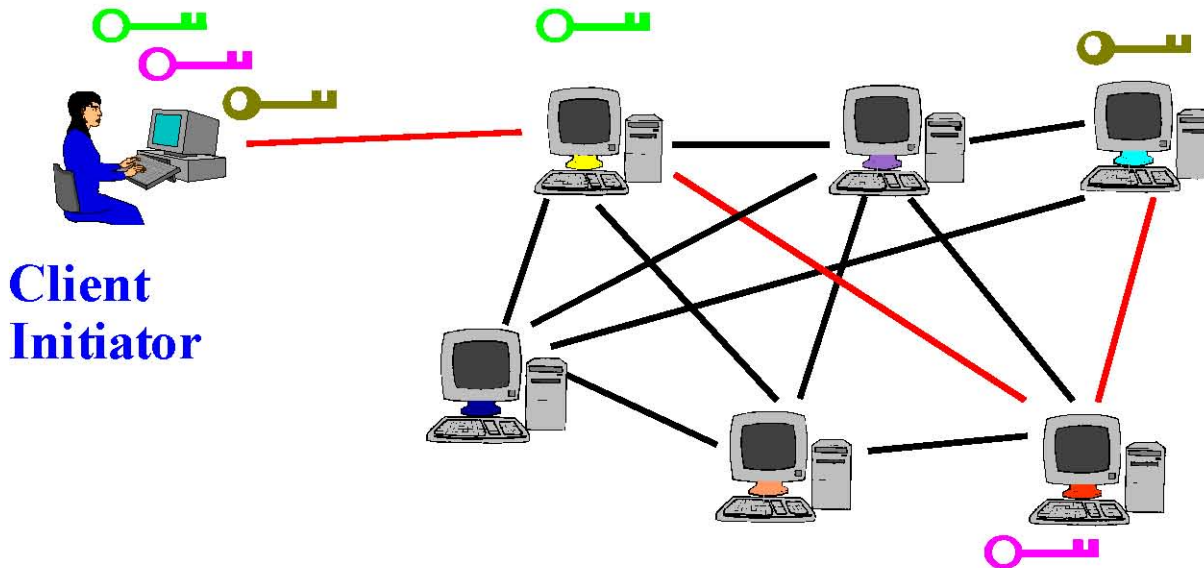

Tor circuit setup (2)

- ▶ Client proxy extends the circuit by establishing a symmetric session key with relay node #2
 - ▶ Tunnel through relay node #1 - don't need !

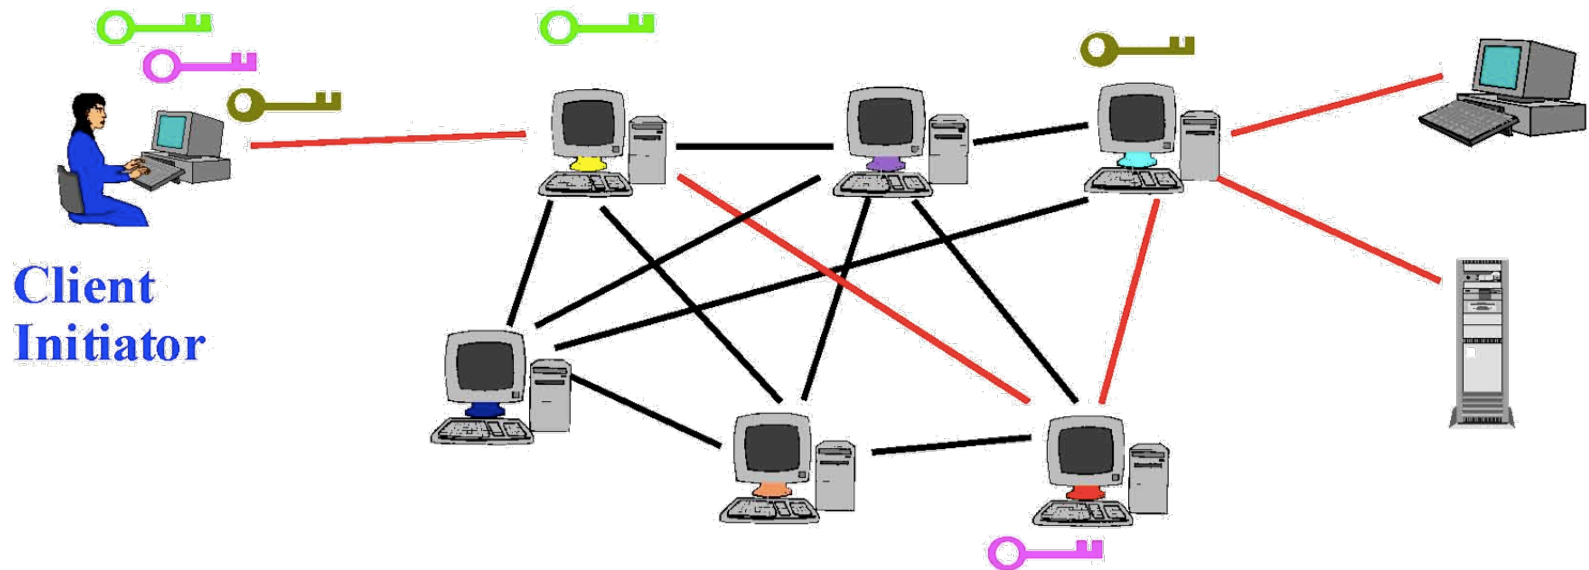

Tor circuit setup (3)

- ▶ Client proxy extends the circuit by establishing a symmetric session key with relay node #3
 - ▶ Tunnel through relay nodes #1 and #2

Using a Tor circuit

- ▶ Client applications connect and communicate over the established Tor circuit
 - ▶ Datagrams decrypted and re-encrypted at each link

Using Tor

- ▶ Many applications can share one circuit
 - ▶ Multiple TCP streams over one anonymous connection
- ▶ Tor router doesn't need root privileges
 - ▶ Encourages people to set up their own routers
 - ▶ More participants = better anonymity for everyone
- ▶ Directory servers
 - ▶ Maintain lists of active relay nodes, their locations, current public keys, etc.
 - ▶ Control how new nodes join the network
 - ▶ “Sybil attack”: attacker creates a large number of relays
 - ▶ Directory servers' keys ship with Tor code

Passive attacks

- ▶ **Observe Traffic Patterns**
 - ▶ Multiplexing minimizes damage
- ▶ **Observe User Content**
 - ▶ Use of Privoxy
- ▶ **Option Distinguishability**
 - ▶ Leads to tracing due to distinct pattern behavior
- ▶ **End-to-end Timing Correlation**
 - ▶ Tor does not hide timing (low-latency requirement)
- ▶ **End-to-end Size Correlation**
 - ▶ Leaky-Pipe Topology
- ▶ **Website Fingerprinting**
 - ▶ New attack as of 2004, semi-defended by mitigation

Active attacks

- ▶ **Compromise Keys**
 - ▶ Mitigated by key rotation and redundant multiple layer encryption. Replacing a node via identity key could theoretically avoid this defense.
- ▶ **Iterated Compromise**
 - ▶ Short lifetimes for circuits
- ▶ **Run Recipient**
 - ▶ Adversary controls end server, which allows him to use Tor to attack the other end. Privoxy would help minimize chance of revealing initiator
- ▶ **Run Onion Proxy**
 - ▶ Compromised OPs compromise all information sent through OP
- ▶ **DoS non-observed nodes**
 - ▶ Only real defense is robustness
- ▶ **Run hostile OR**
 - ▶ Requires nodes at both ends of a circuit to obtain information
- ▶ **Introduce Timing**
 - ▶ Similar to timing discussed in passive version

Active attacks (cont.)

- ▶ **Tag Attacks**
 - ▶ Integrity check mitigates this
- ▶ **Replay Attacks**
 - ▶ Session key changes if replay used
- ▶ **Replace End Server**
 - ▶ No real solution, verify that server is actually server with authentication. Similar to Recipient attack
- ▶ **Smear Attacks**
 - ▶ Good press and exit policies
- ▶ **Hostile Code Distribution**
 - ▶ All Tor releases signed

Directory subversion

- ▶ **Destroy Servers**
 - ▶ Directories require majority rule, or human intervention if more than half destroyed.
- ▶ **Subvert Server**
 - ▶ At worst, cast tie-breaker vote
- ▶ **Subvert Majority of Servers**
 - ▶ Ensure Directories are independent and resistant to attacks
- ▶ **Encourage Dissent in Directory Operators**
 - ▶ People problem, not Tor problem.
- ▶ **Trick Directories**
 - ▶ Server Operators should be able to filter out hostile nodes.
- ▶ **Convince Directories that OR is Functional**
 - ▶ Directory servers should test by building circuit and streams to OR.

Rendezvous point attacks

- ▶ **Many Introduction Point Requests**
 - ▶ IP can block requests with authorization tokens, or require certain amounts of computation per request.
- ▶ **Attack Introduction Point**
 - ▶ Server re-advertises on different IP, or advertise secretly. Attacker must disable all IPs.
- ▶ **Compromise Introduction Point**
 - ▶ Servers should occasionally verify their IPs, and close circuits that flood them.
- ▶ **Compromise Rendezvous Point**
 - ▶ Similar to active attacks against ORs
